

Exploiting Level-of-Detail Perception

- ◆ Nearby viewers
 - ❖ expect full graphical details
 - ❖ accurate structure, position, orientation
 - ❖ update rate → local frame rate
- ◆ Distant viewers
 - ❖ can tolerate less graphical details
 - ❖ less accurate structure, position, orientation
- ◆ User's focus is typically nearby
- ◆ Many inaccuracies cannot even be detected on a fine-resolution display

Multiple-Channel Architecture

- ◆ Multiple independent data channels for each entity

Implementation Examples

- ◆ Client-server
 - ❖ each transmission identifies its channel
 - ❖ server dispatches data from channels to clients
- ◆ Multicast group for each region
 - ❖ assign multiple addresses for each region
 - one group provides all of the entities' high-resolution channels,
 - another group provides all of the entities' low-resolution channels
- ◆ Multicast group for each entity
 - ❖ assign multiple addresses for each entity
- ◆ Different reliabilities to each channel
 - ❖ low-frequency updates are important
 - lost packets can have a significant impact

Selecting the Channels to Provide

- ◆ How many channels to provide for an entity?
 - ❖ more channels: better service for subscribers
 - ❖ each channel imposes a cost (bandwidth and computational)
- ◆ To satisfy the trade-off, three channels for each entity is typically needed
 - ❖ channels provide order-of-magnitude differences in
 - structural and positional accuracy
 - packet rate

Rigid-Body Channel

- ◆ Demands the least bandwidth and computation
- ◆ Represents the entity as a rigid body
- ◆ Ignores changes in the entity's structure
- ◆ Update types:
 - ❖ position
 - ❖ orientation
 - ❖ structure

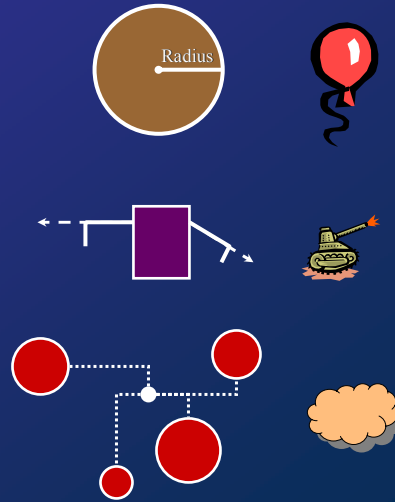

Approximate-Body Channel

- ◆ More frequent position and orientation updates
- ◆ Hosts can render a rough approximation of the entity's dynamic structure
 - ❖ appendages and other articulated parts
- ◆ Provided information is entity-specific
 - ❖ corresponds to the dominant changes of the structure

Common Approximations

- ◆ Radial length
 - ❖ motion towards and away from a centre point
 - ❖ update packets include the current radius
- ◆ Articulation vector
 - ❖ the current direction of the appendage
 - ❖ models a rotating turret, arms and legs
- ◆ Local co-ordinate system points
 - ❖ subset of the entity's significant vertices relative to the entity's local co-ordinate system
 - ❖ the entity is composed of multiple components

Full-Body Channel

- ◆ Highest level of detail
- ◆ High bandwidth and computational requirements
 - ❖ viewer can subscribe to a limited number of full-body channels
- ◆ Frequent transmissions
- ◆ Position and orientation
- ◆ Accurate structure information

Exploiting Temporal Perception

- ◆ Render the entity in an accurate location — albeit slightly out-of-date
- ◆ As long as the local user does not interact, small temporal inaccuracies can be allowed
- ◆ Advantages:
 - ❖ works on WANs having great latency
 - ❖ can enhance packet aggregation
 - ❖ can enhance dead reckoning

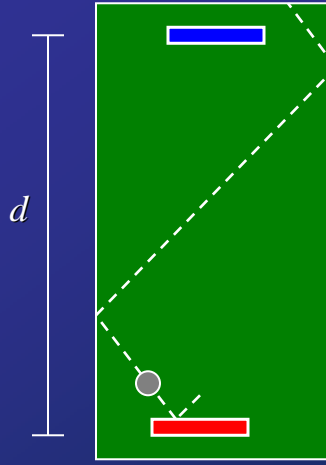

Active and Passive Entities

- ◆ An active entity
 - ❖ takes actions on its own
 - ❖ generates updates
 - ❖ human participants, computer-controlled entities
 - ❖ cannot be predicted typically
 - ❖ rendered using state updates adjusted for the latency
- ◆ A passive entity
 - ❖ reacts to events from the environment, does not generate its own actions
 - ❖ inanimate objects (e.g., rocks, balls, books)
 - ❖ active entities interact with passive entities
 - ❖ rendered according to the latency of its nearest active entity
 - ❖ reacts instantaneously to the actions of a nearby active entity

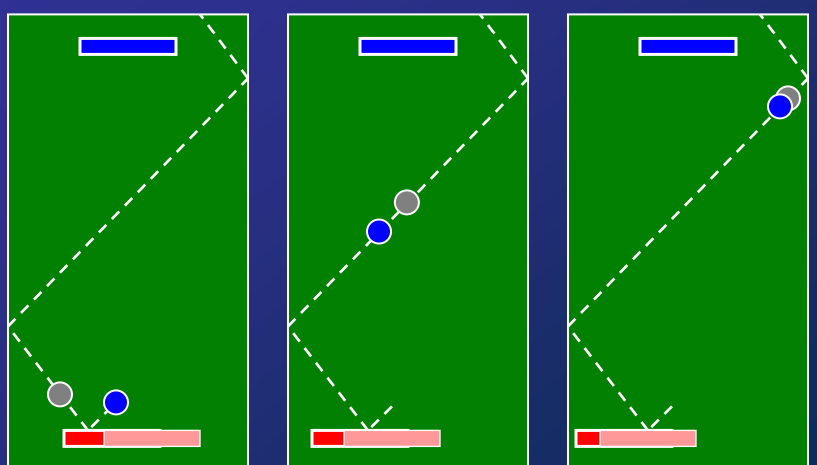

Example: Pong

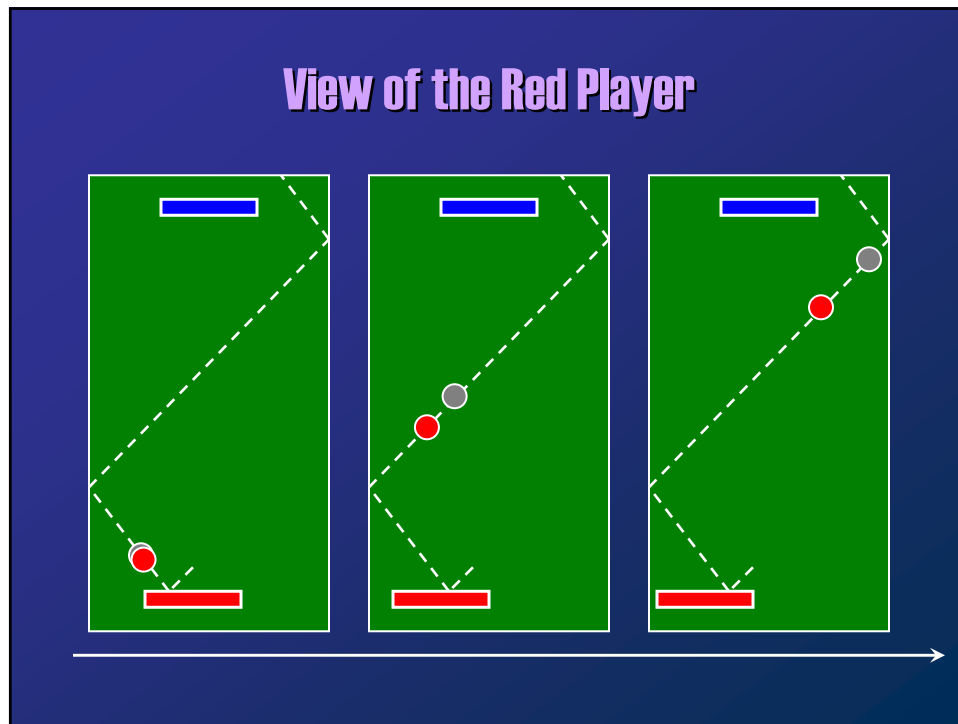

- ◆ Two active entities: paddles
 - ❖ movement unpredictable
- ◆ One passive entity: ball
 - ❖ movement predictable
- ◆ Latency of d seconds

View of the Blue Player

→

Pong: A Summary

- ◆ Each player sees a different representation of the same playing field
- ◆ The ball accelerates as it approaches the local player's paddle
- ◆ The ball decelerates as it approaches the remote player's paddle
- ◆ The ball's rendered position alternates between
 - ❖ the current time
 - meaningful interaction for local player
 - ❖ a past time reference
 - network latency
 - observing meaningful interaction for remote player

3½-Dimensional Playing Field

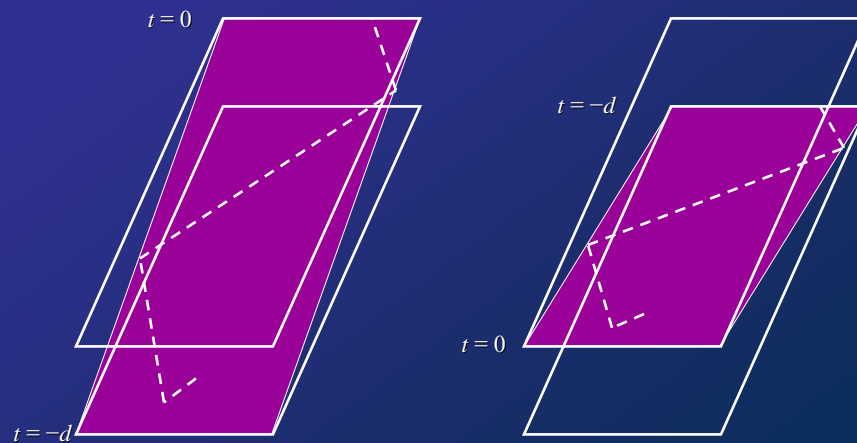

- ◆ Represent each player's perception as a four-dimensional co-ordinate system (x, y, z, t)
 - ❖ x, y, z : the spatial position relative to the local player's current position
 - local player at $(0, 0, 0)$
 - ❖ t : the time associated with rendered information from that position
 - local player rendered at current time: $t = 0$
 - opposing player: $t = -d$

Co-ordinate Systems

Blue Player

Red Player

Properties of the Co-ordinate System

- ◆ The co-ordinate system is defined independently for each player
- ◆ Depends on the player's current position and the delay of arriving information
- ◆ Changes dynamically as the player moves or as the network properties change
- ◆ Defines how a passive object should be rendered
- ◆ Two interacting objects are rendered at the same time reference point
- ◆ Each user perceives all collisions correctly
- ◆ Objects that approach the local user are rendered in the user's time
- ◆ Smooth movement

Generalizing the Local Temporal Contour

- ◆ Limitations:
 - ❖ players are capable of moving along a single axis only
 - ❖ supports two active objects only
- ◆ Generalization to a 4D co-ordinate system requires preserving for the local user:
 - ❖ interacting naturally with passive objects in vicinity
 - ❖ seeing remote interactions (passive-to-passive, passive-to-active) naturally
 - ❖ perceiving smooth motion of remote objects

Local Temporal Contour

- ◆ The local user at $(0, 0, 0)$
- ◆ Each active object is assigned a t value corresponding to its latency
- ◆ Interpolate the contour over all active objects including local
- ◆ Contour defines a suitable t value for each spatial point

Limitations

- ◆ Varying latency can cause entities to (unnaturally) jump forward or backward in time
 - ❖ use averaged latency to dampen the effect
- ◆ What if an update packet is delayed considerably?
 - ❖ predict entity's past position, dead reckoning
- ◆ Computational requirements
 - ❖ compute the contour using only the nearest active entities

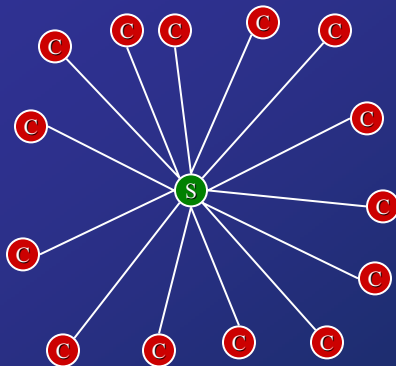

§6.4 Enhancing the System Architecture

- ◆ Change the network software architecture
- ◆ Basic structures: client-server and peer-to-peer
- ◆ Augment and combine basic structures
 - ❖ server clusters
 - partition clients across multiple servers
 - partition the NVE across multiple servers
 - ❖ server hierarchies
 - ❖ peer-server systems

Traditional Client-Server

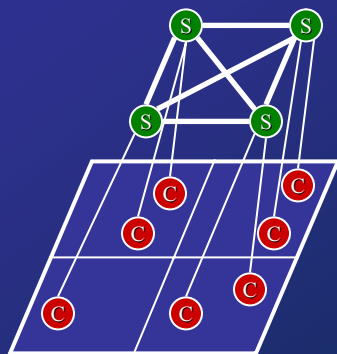

- ◆ Server may act as
 - ❖ broadcast reflector
 - ❖ filtering reflector
 - ❖ packet aggregation server
 - ◆ Scalability problems
 - ❖ all traffic goes through the server
- ⇒ Server clusters

Partitioning Clients across Multiple Servers

- ◆ The servers exchange control messages among themselves
 - ❖ inform the interests of their clients
- ◆ Reduces the workload on each server
- ◆ Incurs a greater latency
- ◆ The total processing and bandwidth requirements are greater

Partitioning the NVE across Multiple Servers

- ◆ Each server manages clients located within a certain region
- ◆ Client communicates with different servers as it moves
- ◆ Eliminates a lot of network traffic
- ◆ Requires advanced configuration
- ◆ Is a region visible from another region?
- ◆ Aggregation servers are a special case of NVE server partitioning
